cancer surveillance research csr is an observational science of cancer data ascertained in population based cohorts notably cancer registries csr is used to track cancer incidence mortality burden prevalence and survivorship quantify cancer differences inform cancer control programs test hypotheses uncover etiologic clues gauge effectiveness of screening and therapy and characterize cancer s natural history and its evolution over time to date most csr studies have relied on a limited set of non parametric statistical tools applied to relatively small datasets currently attempts to scale such studies are surprisingly labor intensive and require specialized expertise advances in biostatistics and data science have the potential to usher in a golden age where more data and better data are universally accessible contemporary methods from biostatistics and data science are rapidly and freely deployable and current knowledge more readily mined to inform both cancer control and cancer research the aim of this research topic is to show how to get there the golden age from the here and now there are three pieces to the equation for advancement data statistics and hypotheses 1 how can information technology and data science facilitate access to and integration of public use cancer data in a format suitable for novel studies of cancer incidence mortality and survivorship how can associated demographic and risk factors data be integrated with cancer surveillance data into the workflows 2 can advances in non parametric statistics and mathematical models especially age period cohort models provide a unified framework for descriptive and hypothesis based analysis of cancer trends and patterns 3 how can information technology and data science help researchers interrogate synthesize and statistically analyze cancer data to inform etiological hypotheses and cancer control programs as well we aim to highlight why this effort is important 4 what are the big

reports the results of an analysis of combined mortality data on 95 673 nuclear industry workers at seven facilities in the usa uk and canada workers at these facilities which include both atomic energy stations and nuclear weapons plants have been monitored in previous studies to determine the health effects of external exposure to ionizing radiation by combining and assessing data from previous studies the present analysis aimed to develop more precise estimates of the risk of radiation induced cancer and thus to strengthen the scientific basis for setting radiation protection standards the study also compared risk estimates among workers with estimates obtained in high dose studies including investigations of atomic bomb survivors and of patients irradiated for therapeutic purposes the results represent the most comprehensive and precise direct assessment to date of the carcinogenic risk of protracted external exposure to generally low doses of ionizing radiation the combined analysis of data on nuclear industry workers found a significant increase in the risk of leukemia and of myeloid leukemia in particular at relatively low dose levels the study also provided an opportunity to examine some of the previously reported associations between low doses of ionizing radiation and mortality from specific cancer types of the 36 cancer types or groupings considered most showed little or no association with radiation exposure apart from leukemia multiple myeloma was the only cancer to exhibit a statistically significant association with radiation dose
